3 Introduction

3.1 Overview

This document describes the GR716-BOARD Development Board. This equipment is intended to be used as a platform for the demonstration of the Cobham Gaisler GR716 RAD Hard Microcontroller.

Furthermore, this board provides developers with a convenient hardware platform for the evaluation and development of software for the GR716 microcontroller.

The GR716 Microcontroller features a fault-tolerant LEON3 SPARC V8 processor, communication interfaces and on-chip ADC, DAC, Power-on-Reset, Oscillator, Brown-out detection, LVDS transceivers, regulators to support for single 3.3V supply, ideally suited for space and other high-rel applications.

The GR716 Microcontroller is a complex device with multifunctional pins whose function depend on the mode of operation and programming of internal registers of the device. This board treats the pins in a generic manner to allow easy access to all the pins and features of the GR716 microcontroller.

![GR716-BOARD Development Board](image)

*Figure 3-1: GR716-BOARD Development Board*
The board contains the following main items as detailed in section 4 of this document:

- size 80 x 100mm
- two 2x32 pin stackable 0.1” headers allowing access to all I/O pins
- connector for single VIN power input (+5V to +12V)
- alternative connector for connections to individual device power supplies
- jumpers for power supply configuration
- on-board regulators converting from VIN to 3.3V & 1.8V
- 256 Mbit SPI memory (Cypress, S25FL256SAGN in 8 pin WSON package)
- socket for crystal (25MHz TBC)
- DIP switch for bootstrap settings
- on-board I2C voltage/current measurement

### 3.2 Handling

**ATTENTION: OBSERVE PRECAUTIONS FOR HANDLING ELECTROSTATIC SENSITIVE DEVICES**

This unit contains sensitive electronic components which can be damaged by Electrostatic Discharges (ESD). When handling or installing the unit observe appropriate precautions and ESD safe practices.

When not in use, store the unit in an electrostatic protective container or bag.

When configuring the jumpers on the board, or connecting/disconnecting cables, ensure that the unit is in an un-powered state.

When operating the board in a 'stand-alone' configuration, the power supply should be current limited to prevent damage to the board or power supply in the event of an over-current situation.

This board is intended for commercial use and evaluation in a standard laboratory environment, nominally, 20°C. All devices are standard commercial types, intended for use over the standard commercial operating temperature range (0 to 70°C).
4 Board Design

4.1 Board Block Diagram

The GR716-BOARD Board provides the electrical functions and interfaces as represented in the block diagram, Figure 4-2.

![GR716-BOARD Board Block Diagram](image)

Figure 4-1: GR716-BOARD Board Block Diagram

Note that not all features and interfaces are available at the same time, and the configuration of on-board resistors plus programming of registers is required to access some of the features.
4.2 Board Mechanical Configuration

The board (80 x 100mm) and can be used 'stand-alone' on the bench-top simply an external +5V power supply connected to connector J2. For mounting of the board on a carrier or expansion board, four M2.5 mounting holes are provided in the corners of the board, as shown in the figure below.

The expansion connectors P1 and P2 of the GR716-BOARD are stacking style connectors having a socket on the bottom side and an extended pin on the top side. In a stand-alone configuration the pins on the top side allow easy access for Logic Analyser or Oscilloscope probing for all the functional microcontroller pins.

Figure 4-2: GR716-BOARD Board Dimensions
The sockets on the bottom side allow the board to be plugged on to a carrier board to conveniently enable further development testing.

The CPCI format board providing GPIO, SPW, Serial (via FTDI-USB) and analog coaxial connector which has been developed for this purpose is shown in Figure 4-3.

Alternatively, the stacking connector concept allows the interface functions to be expanded by stacking the GR716-BOARD to other boards in a concept similar to PC104.

A test board for adding memory (SPI serial, 8 bit parallel FLASH and 8 bit SRAM) is shown in Figure 4-4, and a test board for exercising the Analog features of the GR716 microcontroller is shown in Figure 4-5.

This concept also provides a convenient way for User Defined interface boards to be developed and connected to the GR716-BOARD, if other functions or features are to be demonstrated.
Figure 4-4: GR716-TEST-MEMORY BOARD

Figure 4-5: GR716-TEST-ADCDAC BOARD
4.3 GR716 Microcontroller

The Cobham Gaisler GR716 Microcontroller features a fault-tolerant LEON3 SPARC V8 processor, communication interfaces and on-chip ADC, DAC, Power-on-Reset, Oscillator, Brown-out detection, LVDS transceivers, regulators to support for single 3.3V supply, ideally suited for space and other high-rel applications.

The GR716 Microcontroller is a complex device with many modes of operation. For the details of the interfaces, operation and programming, refer to [RD1].

The GR716 microcontroller is packaged in a 132-pin, 0.635mm pitch Ceramic Quad Flat Pack package (housing: 24 x 24 mm).

Figure 4-6: GR716 Microcontroller Block Diagram

Figure 4-7: GR716 Package
4.4 Memory

The memory configuration installed on the board comprises:

- 256 Mbit SPI serial boot prom (*Cypress, S25FL256SAGN*)

The SPI boot memory is connected directly to the SPIM interface of the *GR716* Microcontroller. Although the SPI memory chip can operate in a x4 data mode, only a x1 data mode is usable with the *GR716*.

4.5 LVDS Interfaces

The GR716 microcontroller provides a set of three LVDS input pairs and three LVDS output pairs which are configurable from software via configuration registers to provide SpaceWire or SPI4SPACE interfaces.

These signals are connected from the *GR716* microcontroller to the Expansion connector, P2.

100 Ohm Termination resistors and fail-safe resistors for the LVDS receiver signals are mounted on the board close to the receiver.
4.6 GPIO

All 64 GPIO pins are connected from the GR716 Microcontroller to the Expansion connector.

These General purpose I/O pins are 3.3V LVCMOS voltage levels.

Note though that most pins have multiple functions and in certain configurations may have different input/output voltage requirements (e.g. ADC and DAC signals). Care must be taken to account for this.

No current limiting or overvoltage protection components are included on the GPIO signals of the GR716-BOARD board. The signals are connected directly from the microcontroller to the expansion connector. Care must therefore be taken to ensure that any external circuitry connected does not exceed the allowable voltage limits for the input/output pins.

4.7 Bootstrap Signals

A number of features of the GR716 microcontroller are required to be set at power-on of the processor, by means of bootstrap pins. A number of GPIO and function pins are pre-defined for this purpose, according to the definition Table 22 of [RD1].

To define the desired setting, an 8 pole, Double-Throw DIP switch (S1), is provided on the board to connect these signals to either a pull-up or a pull-down resistor, or to allow the pin to float.

*Table 1: Bootstrap Resistor Settings*
4.8 Debug Support Unit Interfaces

Program download and debugging to the processor is performed using the GRMON Debug Monitor tool from Cobham Gaisler ([RD4]). The GR716 microcontroller provides a UART based DSU interface for Debug and control of the processor by means of a host terminal, as represented in Figure 4-9.

Four control signals from the Debug Support Unit interface to the processor are implemented:

- DSUTX: Debug UART Transmit
- DSURX: Debug UART Receive
- DSUEN: This signal is pulled high on the board to enable Debugging
- DSUBRE: This signal is pulled low on the board

To connect to a host computer, a small adapter can be used as shown in Figure 4-10.

![Figure 4-9: Debug Support Unit connections](image)

![Figure 4-10: GR716-DSU-USB Adapter](image)
4.9 Oscillators and Clock Inputs

The oscillator and clock scheme for the GR716-BOARD Board is shown in Figure 4-11. Two oscillator inputs are required: CLK for the main system clock, and SPW_CLK for the SpaceWire clock of the microcontroller.

To allow the GR716 Microcontroller to operate in a stand alone manner a crystal is required on the board which is connected to the Crystal oscillator interface for the GR716. On this board the crystal is mounted on a DIL8 socket adapter in order to allow various crystal frequencies to be tested.

This generates an output clock, XO_OUT, which is connected to the CLK and SPW_CLK inputs with jumpers.

In an alternative scenario, it may be preferred to have a separate CLK or SYS_CLK to allow different frequencies to be used. In this case the jumpers can be moved and instead an external 3.3V LVCMOS clock signal provided via the expansion connector.

For more details of the internal Crystal Oscillator, PLL structure and clock gating features of the GR716, please refer to sections 9 and 10 of [RD1].

![Figure 4-11: Board level Clock Distribution Scheme](image-url)
4.10 Power Supply and Voltage Regulation

The power configuration is represented in Figure 4-12.

By means of configuration jumpers, several configurations can be tested:

1. Individual voltages from external bench supplies connected to the screw terminal connector J1 to provide:
   - +VADC (+3V3 nominal)
   - +VREF (+3V3 nominal)
   - +VDAC (+3V3 nominal)
   - +VLVDS (+3V3 nominal)

   This allows individual power supplies to be tested over min/nom/max by varying the supply voltages

   In this case

2. Single VIN (+12V nominal) input supply connector to J1.

3. Single VIN (+12V nominal) input supply connector to J2.

4. VIN provided from external circuitry connected to Expansion connector P2.

With reference to the setting of the jumpers shown in Figure 4-13:

- In case 1, jumpers JP1, JP2, JP3 and JP4 should be set to position 1-2.
- In cases 2,3,4 VIN is regulated with two LMZ21701 micro Point-of-Load regulators to generate a regulated VDDIO (+3.3V) and VDD_CORE (+1.8V). In these cases, jumpers JP1, JP2, JP3 and JP4 should be set to position 2-3.
- **Jumper JP5 (VPLL) should not be installed.** VPLL is provided from the 1V8 voltage generated by the LDO regulator inside the GR716.
- If the **GR716** is to be operated from a **single 3.3V**, and the internal LDO is to be used to generate the VDDCORE voltage of 1.8V then **JP6 should be installed** and **JP7 removed**.
- If the **GR716** is to be operated from **both the POL generated 3.3V and 1.8V** supplies, then **JP6 should be removed** and **JP7 installed**. In this situation, the internal LDO is disabled and VDDCORE voltage of 1.8V is provided from the POL regulator.

At the output of the 3.3V and 1.8V POL regulators, 20 mOhm sense resistors and INA219 Current/Power Monitor circuits with an I2C interface are incorporated on the board. The I2C signals (SDA, SCL) are connected to the Expansion connector P2 to allow the current/voltage to be measured using an I2C master circuit.
Figure 4-12: Power Regulation Scheme
Figure 4-13: Power Supply Configuration Jumpers
4.11  Reset Circuit and Button

The GR716 microcontroller includes an internal RESET circuit with Brown-out detector to reset the processor and its peripherals (see section 8 of [RD1]).

The resulting low reset signal is present on the microcontroller pin \textit{RESET\_OUT\_N}. This signal is connected to the expansion connector, \textit{P2}.

A manual reset of the microcontroller can be generated using the \textit{RESET\_IN\_N} signal. This signal is present on the expansion connector \textit{P2}, and can be driven from an external circuitry if required. A miniature push button switch is provided on the GR716-DSU-USB (Figure 4-10) to pull this signal low, when the button is pressed.

4.12  Watchdog

The GR716 microcontroller includes an internal Watchdog timer function which can be used for the purpose of generating a system reset in the event of a software malfunction or crash. Please refer to [RD1].
5 Setting Up and Using the Board

The board is provided with a default configuration set by bootstrap settings.

For additional information, refer to [RD2] and for information about the Bootstrap signals, refer to section 4.7.

To operate the board stand alone on the bench top, install the power configuration jumpers appropriately, and +12V supply to the board connector J2.

ATTENTION! To prevent damage to board, please ensure that the correct power supply voltage and polarity is used with the board.

Do not exceed +14.5V at the power supply input, as this may damage the board.

The POWER_3V3 and POWER_1V8 power good LED’s should be illuminated indicating that the power supply is present and the board is generating the supply voltages that it requires.

Upon power on, using default bootstrap the processor will start executing instructions beginning at the memory location 0x02000000, which is the start of the PROM. If the PROM is 'empty' or no valid program is installed, the first executed instruction will be invalid, and the processor will halt with an ERROR condition.

To perform program download and software debugging on the hardware it is necessary to use the Cobham Gaisler GRMON3 debugging software, installed on a host PC (as represented in Figure 4-9). Please refer to the GRMON3 documentation for the installation of the software on the host PC (Linux or Windows), and for the installation of the associated hardware dongle.

To perform software download and debugging on the processor, a link from the Host computer to the DSU interface of the board is necessary. As described in section 4.8 this is achieved via the FTDI USB interface.

Program download and debugging can be performed in the usual manner with GRMON3. More information on the usage, commands and debugging features of GRMON3, is given in the GRMON3 Users Manuals and associated documentation, [RD4].
